

Serial Controlled, 8-Channel SPST Switch

Features

- ✦ 8 Separately Controlled SPST Switches
- ✦ SPI-Compatible Serial Interface
- ✦ Accepts $\pm 15\text{V}$ Analog Swings
- ✦ Multiple Devices Can Be Daisy Chained

MAX335

Serial Controlled, 8-Channel SPST Switch

ABSOLUTE MAXIMUM RATINGS

Voltages Referenced to V-

V+	44V
GND	25V
V _L	(GND - 0.3V) to (V+ + 0.3V)
SCLK, $\overline{\text{CS}}$, DIN, DOUT, NO ₋ , COM ₋	V- -2V to V+ +2V or 30mA, whichever occurs first

Continuous Current (any terminal)30mA

Peak Current, NO or COM

(pulsed at 1ms, 10% duty cycle MAX).....100mA

Continuous Power Dissipation (T_A = +70°C) (Note 1)

Narrow Plastic DIP (derate 13.33mW/°C above +70°C) ..1067mW

Wide SO (derate 11.76mW/°C above +70°C)941mW

Narrow CERDIP (derate 12.50mW/°C above +70°C)1000mW

Operating Temperature Ranges

MAX335C_ _0°C to +70°C

MAX335E_ _-40°C to +85°C

MAX335MRG-55°C to +125°C

Storage Temperature Range-65°C to +160°C

Lead Temperature (soldering, 10sec)+300°C

Note 1: All leads are soldered or welded to PC boards.

Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

ELECTRICAL CHARACTERISTICS

(V_L = +5V ±10%, V+ = 15V, V- = -15V, T_A = T_{MIN} to T_{MAX}, unless otherwise noted. Typical values are at T_A = +25°C.)

PARAMETER	SYMBOL	CONDITIONS		MIN	TYP	MAX	UNITS

Detailed Description

Serial Digital Interface

Basic Operation

Refer to Figure 2. The MAX335 interface can be thought of as an 8-bit shift register controlled by \overline{CS} . While \overline{CS} is low, input data appearing at DIN is clocked into the shift register synchronous with SCLK's rising edge. The data is an 8-bit word, each bit controlling one of eight switches in the MAX335 (Table 1). DOUT is the output of the shift register, with data appearing synchronous with SCLK's falling edge. Data at DOUT is simply the input data delayed by eight clock cycles.

When shifting the input data, D7 is the first bit in and out of the shift register. While shifting data, the switches remain in their original configuration. When the 8 bits of data have been shifted in, \overline{CS} is brought high. This

updates the new switch configuration and inhibits further data from entering the shift register. Transitions at DIN and SCLK have no effect when \overline{CS} is high, and DOUT holds the last bit in the shift register.

The MAX335 three-wire serial interface is compatible with the SPI™ and Microwire™ standards. If interfacing with a Motorola processor serial interface, set CPOL = 0. The MAX335 is considered a slave device (Figures 2 and 3). Upon power-up, the shift register contains all zeros, and all switches are off.

The latch that drives the analog switch is only updated on the rising edge of \overline{CS} when SCLK is low. If SCLK is high when \overline{CS} rises, the latch will not be updated until SCLK goes low. The CPOL = 1, CPHA = 1 SPI configuration does not update the latch correctly.

Daisy Chaining

For a simple interface using several MAX335s, "daisy chain" the shift registers as shown in Figure 5. The \overline{CS} pins of all devices are connected together, and a stream of data is shifted through the MAX335s in series. When \overline{CS} is brought high, all switches are updated simultaneously. Additional shift registers may be included anywhere in series with the MAX335 data chain.

Addressable Serial Interface

When several serial devices are configured as slaves, addressable by the processor, DIN pins of each MAX335 are connected together (Figure 6). Address decode logic individually controls \overline{CS} of each slave device. When a slave is selected, its \overline{CS} is brought low, data is shifted in, and \overline{CS} is brought high to latch the data. Typically, only one slave is addressed at a time. DOUT is not used.

Digital Feedthrough

Digital feedthrough energy measures 100nV-sec, which means that with no filtering at the signal channel, feedthrough from a sharply rising clock edge into an unfiltered switch channel can be measured at 1Vp-p for 100ns. However, even 100pF capacitance in the switch channel, when combined with the switch resistance, yields a filter that reduces this transient to 10mVp-p typical. To reduce digital feedthrough, hysteresis (150mV typ) was added to the SCLK input so triangle or sine waves may be used.

MAX335

Applications Information

8 x 1 Multiplexer

To use the MAX335 as an 8 x 1 multiplexer, tie all drains together (COM0 to COM7); the mux inputs now source each switch (NO0 to NO7). Input a single 0V to +3V pulse at DIN. As this is clocked through the register by SCLK, each switch will sequence on one at a time.

4-2 Differential Multiplexer

To use the MAX335 as a 4-2 differential multiplexer, tie COM0 through COM3 together and COM4 through COM7 together. Differential inputs will be the source inputs as follows: (NO0, NO4), (NO1, NO5), (NO2, NO6), (NO3, NO7). Figure 7 shows the serial input control at DIN required to turn on two switches making a differential multiplexer.

Figure 7. Differential Multiplexer Input Control

\overline{CS} is held low for four clock pulses; the first pulse is clocked into the fifth switch position as the second pulse is clocked into the first switch position. \overline{CS} is pulled high to update switches; then \overline{CS} is pulled low, and SCLK advances pulses to S1 and S5 positions, where \overline{CS} is pulled high to update, etc.

SPDT Switches

Tie COM0 to NO1 so that NO0 and COM1 are now inputs and COM0/NO1 is the common output. SP is common output. Up to four SPDT switches can be made from each MAX335. Multiples of four or more can be made by daisy chaining devices. In Figure 8, DIN is a pulse train. Again, \overline{CS} is held low to clock in pulses and \overline{CS} is pulled high to update; \overline{CS} is held low to shift pulses, then pulled high to update, etc.

Figure 8. Serial-Input Control for SPDT Switch

Reset Function

Pulsing V_L below +0.8V initiates the power-up reset function. The switches are set to the off position, and the serial shift register is reset to all zeros.

Power-Supply Operation

The MAX335 operates with $V = \pm 4.5V$ to $\pm 20V$ and $V_L = +5V$. With V_- tied to ground, the part operates with $V_+ = +10V$ to $+30V$.

The V_L supply sets TTL input compatibility at a 1.6V switching threshold. As V_L is raised, the switching threshold is raised, so the part is no longer TTL compatible. The MAX335 also operates with a single power supply: $V_L = V_+$ and $V_- = 0V$. With V_L tied to V_+ , the V_L supply cannot be used as a reset function.

Chip Topography

TRANSISTOR COUNT: 387

SUBSTRATE CONNECTED TO V_+ .
